

Voltage sag solution with energy storage

In [18, 19], it clearly shows that 80% of the power quality complaints reported are of Voltage Sag. Voltage Sag or Voltage Dip (IEC term) is defined by the IEEE 1159 as the decrease in the RMS voltage level to 10%-90% (1%-90% for EN 50,160) of nominal, at the power frequency for durations of 1 cycle to one (1) minute.

Also referred to as voltage dips, voltage sags are brief reductions in electrical voltage by at least 10%. As defined by the IEC 61000-4-30 standard, the voltage sag lasts for less than one minute yet longer than eight milliseconds. The magnitude of a sag ranges between 10% and 90% of the normal Root Mean Square (RMS) voltage at 60Gz.

The difference between sag and dip is that sag refers to a more significant reduction, typically between 10-90% of the nominal voltage level. In contrast, a dip is a small reduction in voltage, normally less than 10% of the minor level. The duration of a voltage sag can vary depending on the cause, but it usually lasts for a few cycles or seconds.
